Faculty of Science and Engineering

END OF SEMESTER ASSESSMENT PAPER

MODULE CODE: MS4327

SEMESTER: Spring 2014

MODULE TITLE: Optimisation

DURATION OF EXAMINATION: $2\frac{1}{2}$ hours

LECTURER: Dr. J. Kinsella

GRADING SCHEME: 20% +80%

EXTERNAL EXAMINER: Prof. T. Myers

INSTRUCTIONS TO CANDIDATES: Answer four questions correctly for full marks; 80%. See the Appendix at the end of the paper for some useful results.

- 1 (a) Suppose that a function $f : \mathbb{R}^n \rightarrow \mathbb{R}$ is C^1 on \mathbb{R}^n and has gradient $\nabla f(\mathbf{x}) \equiv \mathbf{g}(\mathbf{x})$. If a vector \mathbf{p} satisfies the condition $\mathbf{p}^\top \mathbf{g}(\mathbf{x}) < 0$, \mathbf{p} is called a “descent direction” for f at \mathbf{x} . Explain carefully the importance of this definition for optimisation algorithms — justifying any statement that you make. 4
- (b) Suppose that $f : \mathbb{R}^n \rightarrow \mathbb{R}$ is C^1 and \mathbf{p}_k is a descent direction at \mathbf{x}_k . Assume that f is bounded below along the ray $\{\mathbf{x}_k + \alpha \mathbf{p}_k | \alpha > 0\}$. Show that if $0 < c_1 < c_2 < 1$ there exist step lengths α satisfying the Wolfe conditions Eqs. 13a and 13b. 12
- (c) Draw a sketch to illustrate your proof. 4
- (d) Show that if $c_1 > \frac{1}{2}$, a line search satisfying the Wolfe conditions would exclude the minimiser of a strictly convex quadratic objective function so the restriction $c_1 \leq \frac{1}{2}$ is reasonable. 5
- Hint: write $\phi(\alpha) = \phi_0 + \alpha \phi'_0 + \frac{1}{2} \alpha^2 \phi''_0$, find the α -range determined by the first Wolfe condition and compare with α^* , the α -value that minimises $\phi(\alpha)$. Take $\phi''_0 > 0$ as given f strictly convex.
- 2 (a) Prove Zoutendijk’s Theorem (Theorem 1 in Appendix C) 15
- (b) Explain briefly the significance of the result. 1
- (c) Suppose that search directions \mathbf{p}_k are generated using a Newton-like method: $\mathbf{p}_k = -\mathbf{B}_k^{-1} \mathbf{g}(\mathbf{x}_k)$ where \mathbf{B}_k is symmetric and positive definite. For any matrix \mathbf{A} let $\|\mathbf{A}\|$ be the matrix 2-norm, equal for real symmetric matrices to the absolute value of the largest eigenvalue of \mathbf{A} . Show that if $\|\mathbf{B}_k\| \|\mathbf{B}_k^{-1}\| \leq M$ for all k then $\cos \theta_k \geq 1/M$ where θ_k is defined in Appendix C. 8
- (d) Use Zoutendijk’s Theorem above to show that in this case $\lim_{k \rightarrow \infty} \|\mathbf{g}(\mathbf{x}_k)\| = 0$. 1

3 (a) Quadratic convergence for a sequence of vectors $\{\mathbf{x}_k\}_{k=1}^{\infty} \in \mathbb{R}^n$ is defined in Appendix D.

(i) Show that quadratic convergence to a point \mathbf{x}^* implies that the error $\epsilon_k \equiv \|\mathbf{x}_k - \mathbf{x}^*\|$ is less than or equal to $\frac{1}{M} (M\epsilon_0)^{2^k}$ where ϵ_0 is the starting value of the error. 4

(ii) If $M < 1/\epsilon_0$ what can you conclude? Explain carefully. 1

(b) Let $f: \mathbb{R}^n \rightarrow \mathbb{R}$ be C^3 and let the point \mathbf{x}^* satisfy $\nabla f(\mathbf{x}^*) \equiv \mathbf{g}(\mathbf{x}^*) = \mathbf{0}$ and $\nabla^2 f(\mathbf{x}^*) \equiv \mathbf{H}(\mathbf{x}^*)$ is positive definite. Let $R = \|\mathbf{x}_0 - \mathbf{x}^*\|$ be the distance from the start point \mathbf{x}_0 to \mathbf{x}^* . Assume that R is small enough for the condition $R < \frac{1}{k_1 k_2}$ to hold for some $k_1, k_2 > 0$ defined by the two conditions:

(i) the inverse Hessian is bounded in norm: $\|\mathbf{H}^{-1}(\mathbf{x})\| \leq k_1$

(ii) the remainder term in a second-order Taylor expansion of $g(\mathbf{x}^*)$ centred at \mathbf{x} is uniformly bounded: $\|g(\mathbf{x}^*) - g(\mathbf{x}) - \mathbf{H}(\mathbf{x})(\mathbf{x}^* - \mathbf{x})\| \leq k_2 \|\mathbf{x}^* - \mathbf{x}\|^2$

for each \mathbf{x} inside the ball $\mathcal{B} = \{\|\mathbf{x} - \mathbf{x}^*\| \leq R\}$.

Show that, under these assumptions,

(i) that the sequence of \mathbf{x} vectors generated by Newton's method ($\mathbf{x}_{k+1} = \mathbf{x}_k + \mathbf{p}_k$ with $\mathbf{p}_k = -\mathbf{H}^{-1}(\mathbf{x}_k)\mathbf{g}(\mathbf{x}_k)$) converges to \mathbf{x}^* . 12

(ii) that the convergence is quadratic. 2

(c) Let \mathbf{x}^* be a local minimum for f on for an open ball $\mathcal{B}(\mathbf{x}^*)$ centred at \mathbf{x}^* (of radius R , say). It can be shown that, $\forall \mathbf{x} \in \mathcal{B}$,

$$\|\mathbf{x} - \mathbf{x}^*\| \leq \frac{\|\nabla f(\mathbf{x})\|}{m} \quad (1)$$

$$f(\mathbf{x}) - f(\mathbf{x}^*) \leq \frac{\|\nabla f(\mathbf{x})\|^2}{m}. \quad (2)$$

(i) Show that, as a consequence, if the stopping criterion is $\|\nabla f(\mathbf{x})\| \leq \epsilon$ for some small quantity ϵ , then if the stop criterion on the gradient holds at two successive points \mathbf{x} and \mathbf{x}' that: 4

$$\|\Delta \mathbf{x}\| \equiv \|\mathbf{x} - \mathbf{x}'\| \leq \frac{2\epsilon}{m} \quad (3)$$

and

$$|\Delta f| \equiv |f(\mathbf{x}) - f(\mathbf{x}')| \leq \frac{2\epsilon^2}{m}. \quad (4)$$

- (ii) If I choose the stop criterion $|\Delta f| \leq K\varepsilon$ (where K is some constant such as 10 or $|f(x_0)|$ and $\varepsilon = \varepsilon_M$ — machine epsilon), what corresponding stop criteria should I choose for $\|\nabla f\|$ and $\|\Delta x\|$ based on (3) and (4) in Q3.(c)(i)? 2
- 4 (a) Prove the Sherman-Morrison-Woodbury formula for the inverse of a matrix $A + \Delta A$ — stated in App. E. 6
- (b) Given the DFP update formula:

$$\mathbf{DFP}: \quad H_{k+1} = (I - \gamma_k y_k s_k^T) H_k (I - \gamma_k s_k y_k^T) + \gamma_k y_k y_k^T, \quad (5)$$

where

$$\gamma_k = \frac{1}{y_k^T s_k}, \quad s_k = x_{k+1} - x_k \quad \text{and} \quad y_k = \nabla f(x_{k+1}) - \nabla f(x_k)$$

show that the DFP-update formula may be written as $H_{k+1} = H_k + \Delta H_k$, with 6

$$\Delta H_k = R S R^T,$$

where

$$R = [y_k \quad H s_k], \quad S = \gamma_k \begin{bmatrix} 1 + \gamma_k s_k^T H_k s_k & -1 \\ -1 & 0 \end{bmatrix}.$$

- (c) Apply the SMW formula from part (a) to the formula $H_{k+1} = H_k + \Delta H_k$ from part (b) to derive the following equation for the update of the inverse Hessian approximation, J_k that corresponds to the DFP update of H_k in Eq. 5; 13

$$\mathbf{DFP - Inverse} \quad J_{k+1} = J_k - \frac{J_k y_k y_k^T J_k}{y_k^T J_k y_k} + \frac{s_k s_k^T}{y_k^T s_k}. \quad (6)$$

Remember that for any 2×2 matrix

$$\begin{bmatrix} a & b \\ c & d \end{bmatrix}^{-1} = \frac{1}{(ad - bc)} \begin{bmatrix} d & -b \\ -c & a \end{bmatrix}.$$

- 5 Consider the general equality-constrained problem (21) as defined in App. G.

- (a) Show that the penalty function $F^k(x)$ defined in (20) in App. F has the property that the (unconstrained) minima x_k of F^k converge to a local minimum x^* . 10

- (b) Prove the KKT first-order necessary conditions (23a) and (23b) in App. I for an **equality**-constrained problem . 10
- (c) Finally; prove that when inequality constraints are introduced, the extra condition $\lambda_i^* \geq 0$ for all $i \in \mathcal{I}$ is necessary for \mathbf{x}^* to be an optimal solution of (22) in App. H. Define the functions $\mathbf{c}_i^-(\mathbf{x}) = \min\{0, \mathbf{c}_i(\mathbf{x})\}$, $j \in \mathcal{I}$. Obviously $\mathbf{c}_i^-(\mathbf{x}) \leq 0$, $j \in \mathcal{I}$. Adapt (without repeating the details) your argument for part (b) to show that $\lambda_i^* = -\lim_{k \rightarrow \infty} k \mathbf{c}_i^-(\mathbf{x}_k)$, $i \in \mathcal{I}$. 5

6 Consider the equality-constrained Quadratic Program (Q.P.):

$$\min_{\mathbf{x}} q(\mathbf{x}) = \frac{1}{2} \mathbf{x}^T \mathbf{Q} \mathbf{x} + \mathbf{x}^T \mathbf{d}, \quad (7a)$$

$$\text{subject to } \mathbf{a}_i^T \mathbf{x} = \mathbf{b}_i, \quad i = 1, \dots, k \quad (7b)$$

- (a) Let \mathbf{A} be the matrix s.t. the vectors $\{\mathbf{a}_i\}_{i \in \mathcal{E}}$ are the columns of \mathbf{A}^T . Writing the set of k equality constraints (7b) as the matrix equation $\mathbf{A} \mathbf{x} - \mathbf{b} = \mathbf{0}$, show that if \mathbf{x}^* is a local minimum then the KKT conditions (Appendix I) require that there must be a vector λ^* of Lagrange multipliers such that the following system of equations is satisfied: 4

$$\begin{bmatrix} \mathbf{Q} & \mathbf{A}^T \\ \mathbf{A} & \mathbf{0} \end{bmatrix} \begin{bmatrix} \mathbf{x}^* \\ -\lambda^* \end{bmatrix} = \begin{bmatrix} -\mathbf{d} \\ \mathbf{b} \end{bmatrix} \quad (8)$$

- (b) If we write $\mathbf{x}^* = \mathbf{x}_0 + \mathbf{p}$, where \mathbf{x}_0 is any estimate of the solution and \mathbf{p} the required step to the solution, show that (8) can be re-written as: 2

$$\begin{bmatrix} \mathbf{Q} & \mathbf{A}^T \\ \mathbf{A} & \mathbf{0} \end{bmatrix} \begin{bmatrix} -\mathbf{p} \\ \lambda^* \end{bmatrix} = \begin{bmatrix} \mathbf{g} \\ \mathbf{r} \end{bmatrix} \quad (9)$$

where the residual $\mathbf{r} = \mathbf{A} \mathbf{x}_0 - \mathbf{b}$, $\mathbf{g} = \mathbf{Q} \mathbf{x}_0 + \mathbf{d}$ (the gradient of $q(\mathbf{x}_0)$) and $\mathbf{p} = \mathbf{x}^* - \mathbf{x}_0$.

- (c) Show that this block matrix equation can be reduced to the problem of solving

$$\left(\mathbf{A} \mathbf{Q}^{-1} \mathbf{A}^T \right) \lambda^* = \left(\mathbf{A} \mathbf{Q}^{-1} \mathbf{g} - \mathbf{r} \right). \quad (10)$$

for λ^* and then solving

$$-\mathbf{Q} \mathbf{p} + \mathbf{A}^T \lambda^* = \mathbf{g} \quad (11)$$

for \mathbf{p} . 2

(See the following page for part (d) of this question.)

(d) Solve the **Inequality**-constrained QP:

$$\min_{\mathbf{x} \in \mathbb{R}^2} \mathbf{q}(\mathbf{x}) \text{ subject to } \mathbf{A}\mathbf{x} \geq \mathbf{b}, \quad (12)$$

with $\mathbf{q}(\mathbf{x}) = \frac{1}{2}\mathbf{x}^T\mathbf{Q}\mathbf{x} + \mathbf{d}^T\mathbf{x}$ where $\mathbf{Q} = \begin{bmatrix} 5 & -3 \\ -3 & 7 \end{bmatrix}$ and $\mathbf{d} = \begin{bmatrix} 1 \\ -9 \end{bmatrix}$

with $\mathbf{A} = \begin{bmatrix} -1 & 3 \\ 1 & 1 \end{bmatrix}$ and $\mathbf{b} = \begin{bmatrix} 9 \\ -5 \end{bmatrix}$ using the following steps.

- (i) Using the fact that $\mathbf{Q}^{-1} = \frac{1}{26} \begin{bmatrix} 7 & 3 \\ 3 & 5 \end{bmatrix}$ find \mathbf{x}_u , the **unconstrained** minimum of $\mathbf{q}(\mathbf{x})$, ($\nabla f(\mathbf{x}_u) = 0$). 1
- (ii) Confirm that the first constraint, $-\mathbf{x}_1 + 3\mathbf{x}_2 \geq 9$, is violated at \mathbf{x}_u while the second, $\mathbf{x}_1 + \mathbf{x}_2 \geq -5$ is inactive at \mathbf{x}_u . 1
- (iii) Check that $\mathbf{x}_0 = \begin{bmatrix} -6 \\ 1 \end{bmatrix}$ is the vertex common to the two constraints — the intersection point of the two lines. (A rough sketch of the two lines is useful in the following.) 1
- (iv) Calculate the gradient $\mathbf{g}(\mathbf{x}_0) = \mathbf{Q}\mathbf{x}_0 + \mathbf{d}$. 1
- (v) To solve the Inequality constrained problem, use the procedure in part (c) of this question to solve the **Equality**-constrained QP

$$\min_{\mathbf{x} \in \mathbb{R}^2} \mathbf{q}(\mathbf{x}) \text{ subject to } \tilde{\mathbf{A}}\mathbf{x} = \tilde{\mathbf{b}} \quad (13)$$

starting at the point \mathbf{x}_0 , using the following steps:

- A. Explain why the second constraint ($\mathbf{x}_1 + \mathbf{x}_2 \geq -5$) may be dropped from the working set \mathcal{W} . 3
- B. Write a numerical (not algebraic) matrix expression for λ . (**Do not perform the matrix arithmetic.**) Note that $\mathbf{r} = \mathbf{0}$ at \mathbf{x}_0 as both constraints are active at \mathbf{x}_0 . 1
- C. Taking $\lambda = 64/17$, write a matrix expression for \mathbf{p} . (**Again, do not perform the matrix arithmetic.**) 1
- D. Taking $\mathbf{p} = \frac{40}{17} \begin{bmatrix} 3 \\ 1 \end{bmatrix}$, check that $\tilde{\mathbf{A}}\mathbf{p} = \mathbf{0}$. 1
- E. Calculate the new point $\mathbf{x}_1 = \mathbf{x}_0 + \mathbf{p}$ to two decimal places. 1
- F. Explain why $\tilde{\mathbf{A}}\mathbf{x}_1 = \tilde{\mathbf{b}}$ (no arithmetic). 1
- G. Is \mathbf{x}_1 feasible for both constraints? 1
- H. Is either constraint active at \mathbf{x}_1 ? 1
- I. Explain carefully why the point \mathbf{x}_1 is optimal for the full Inequality constrained problem. 3

Appendix of Results

A The Wolfe conditions for the step length α in a line search require that

$$f(\mathbf{x}_k + \alpha \mathbf{p}_k) \leq f(\mathbf{x}_k) + c_1 \alpha \mathbf{p}_k^T \mathbf{g}(\mathbf{x}_k), \quad (13a)$$

$$\mathbf{p}_k^T \mathbf{g}(\mathbf{x}_k + \alpha \mathbf{p}_k) \geq c_2 \mathbf{p}_k^T \mathbf{g}(\mathbf{x}_k) \quad (13b)$$

where $\mathbf{g}(\mathbf{x}) \equiv \nabla f(\mathbf{x})$ and $0 < c_1 < c_2 < 1$. The **strong** Wolfe conditions replace (13b) by

$$|\mathbf{p}_k^T \mathbf{g}(\mathbf{x}_k + \alpha \mathbf{p}_k)| \leq c_2 |\mathbf{p}_k^T \mathbf{g}(\mathbf{x}_k)|. \quad (14)$$

B In terms of a “line” function $\phi(\alpha) \equiv f(\mathbf{x} + \alpha \mathbf{p})$; the Wolfe conditions for the step length α in a line search require that

$$\phi(\alpha) \leq \phi(0) + c_1 \alpha \phi'(0), \quad (14a)$$

$$\phi'(\alpha) \geq c_2 \phi'(0) \quad (14b)$$

where $0 < c_1 < c_2 < 1$. The **strong** Wolfe conditions replace (14b) by

$$|\phi'(\alpha)| \leq c_2 |\phi'(0)|. \quad (15)$$

C **Theorem 1 (Zoutendijk)** Consider any iteration of the form $\mathbf{x}_{k+1} = \mathbf{x}_k + \alpha_k \mathbf{p}_k$, where \mathbf{p}_k is a descent direction and α_k satisfies the Wolfe conditions Eqs. 13a and 13b in Appendix A above. Suppose that f is bounded below in \mathbb{R}^n and that f is C^1 in an open set \mathcal{N} containing the level set $\mathcal{L} \equiv \{\mathbf{x} : f(\mathbf{x}) \leq f(\mathbf{x}_0)\}$, where \mathbf{x}_0 is the starting point. Also assume that $\mathbf{g}(\mathbf{x})$, the gradient of f , is Lipschitz continuous on \mathcal{N} , i.e. there exists a constant L such that

$$\|\mathbf{g}(\mathbf{x}) - \mathbf{g}(\bar{\mathbf{x}})\| \leq L \|\mathbf{x} - \bar{\mathbf{x}}\|, \quad \text{for all } \mathbf{x}, \bar{\mathbf{x}} \in \mathcal{N}. \quad (16)$$

Then

$$\sum_{k \geq 0} \cos^2 \theta_k \|\mathbf{g}(\mathbf{x}_k)\|^2 < \infty, \quad (17)$$

where θ_k is the angle between \mathbf{p}_k and the steepest descent direction $-\mathbf{g}(\mathbf{x}_k)$.

D A sequence $\{\mathbf{x}_k\}_{k=1}^{\infty}$ that converges to a point \mathbf{x}^* has quadratic convergence if for some positive constant M ;

$$\frac{\|\mathbf{x}_{k+1} - \mathbf{x}^*\|}{\|\mathbf{x}_k - \mathbf{x}^*\|^2} \leq M, \quad \text{for all } k \text{ sufficiently large.} \quad (18)$$

E The Sherman-Morrison-Woodbury formula states that if a square non-singular matrix \mathbf{A} is updated by

$$\mathbf{A}' = \mathbf{A} + \Delta\mathbf{A}, \quad \text{where } \Delta\mathbf{A} = \mathbf{R}\mathbf{S}\mathbf{T}^\top$$

where \mathbf{R}, \mathbf{T} are $n \times p$ matrices for $1 < p < n$ and \mathbf{S} is $p \times p$ then

$$\mathbf{A}'^{-1} \equiv (\mathbf{A} + \Delta\mathbf{A})^{-1} = \mathbf{A}^{-1} - \mathbf{A}^{-1}\mathbf{R}\mathbf{U}^{-1}\mathbf{T}^\top\mathbf{A}^{-1}, \quad (19)$$

where $\mathbf{U} = \mathbf{S}^{-1} + \mathbf{T}^\top\mathbf{A}^{-1}\mathbf{R}$.

F Let \mathbf{x}^* be a local minimum of the equality-constrained optimisation problem defined in App. G. For each positive integer k , define a **penalty function**

$$F^k(\mathbf{x}) = f(\mathbf{x}) + \frac{k}{2}\|\mathbf{c}(\mathbf{x})\|^2 + \frac{\alpha}{2}\|\mathbf{x} - \mathbf{x}^*\|^2, \quad (20)$$

where $\alpha > 0$ is arbitrary.

G The general equality constrained optimisation problem is:

$$\min_{\mathbf{x} \in \mathbb{R}^n} f(\mathbf{x}) \quad \text{subject to} \quad \mathbf{c}_i(\mathbf{x}) = 0, \mathbf{i} \in \mathcal{E} \quad (21)$$

H The general inequality constrained optimisation problem is:

$$\min_{\mathbf{x} \in \mathbb{R}^n} f(\mathbf{x}) \quad \text{subject to} \quad \begin{cases} \mathbf{c}_i(\mathbf{x}) = 0 & \mathbf{i} \in \mathcal{E}, \\ \mathbf{c}_i(\mathbf{x}) \geq 0 & \mathbf{i} \in \mathcal{I} \end{cases} \quad (22)$$

I The first-order KKT necessary conditions for a point \mathbf{x}^* with optimal multipliers λ^* to be a local solution of an inequality-constrained minimisation problem are as follows: Suppose that \mathbf{x}^* is a local solution of a general constrained optimisation (as in App. H) problem and that the LICQ holds at \mathbf{x}^* (i.e. the active constraint gradients are linearly independent). Then there is a Lagrange multiplier vector λ^* , with components $\lambda_i^*, \mathbf{i} \in \mathcal{E} \cup \mathcal{I}$, such that the following conditions are satisfied at $(\mathbf{x}^*, \lambda^*)$

$$\nabla_{\mathbf{x}}\mathcal{L}(\mathbf{x}^*, \lambda^*) = 0, \quad (23a)$$

$$\mathbf{c}_i(\mathbf{x}^*) = 0, \quad \text{for all } \mathbf{i} \in \mathcal{E}, \quad (23b)$$

$$\mathbf{c}_i(\mathbf{x}^*) \geq 0, \quad \text{for all } \mathbf{i} \in \mathcal{I}, \quad (23c)$$

$$\lambda_i^* \geq 0, \quad \text{for all } \mathbf{i} \in \mathcal{I}, \quad (23d)$$

$$\lambda_i^* \mathbf{c}_i(\mathbf{x}^*) = 0, \quad \text{for all } \mathbf{i} \in \mathcal{E} \cup \mathcal{I} \quad (23e)$$

where $\mathcal{L}(\mathbf{x}, \lambda) \equiv f(\mathbf{x}) - \sum_{\mathbf{i} \in \mathcal{E} \cup \mathcal{I}} \lambda_i \mathbf{c}_i(\mathbf{x})$.

J The (revised) Simplex algorithm may be stated as:

Algorithm 1

Given $\mathcal{B}, \mathcal{N}, x_{\mathcal{B}} = B^{-1}b \geq 0, x_{\mathcal{N}} = 0$;

Solve $B^T \lambda = c_{\mathcal{B}}$ for λ

$s_{\mathcal{N}} = c_{\mathcal{N}} - N^T \lambda$; (pricing)

if $s_{\mathcal{N}} \geq 0$

then STOP; (optimal point found)

fi

Select $q \in \mathcal{N}$ with $s_q < 0$ as the entering index

Solve $Bd = A_q$ for d ;

if $d \leq 0$

then STOP; (problem is unbounded)

fi

Calculate $x_q^+ = \min_{i|d_i > 0} (x_{\mathcal{B}})_i / d_i$ and use p to denote the minimizing i ;

Update $x_{\mathcal{B}}^+ = x_{\mathcal{B}} - dx_q^+, x_{\mathcal{N}}^+ = (0, \dots, 0, x_q^+, 0, \dots, 0)^T$;

Change \mathcal{B} by adding q and removing the basic variable corresponding to column p of \mathcal{B} .
